(a) Evaluate the following expressions.

```
a <- ((93)^2 - 164) / (46^3 + 189)
b <- 376 - (23^2) / 4
c <- (59 + 48^2) / ((-9) + 22^2)
d <- (-16 + 55^2) / 13 + 29^2
e <- 18^4 - 16^3 + 14^2 - 12
c(a, b, c, d, e)
```

```
## [1] 8.700333e-02 2.437500e+02 4.974737e+00 1.072462e+03 1.010640e+05
```

(b) Evaluate  $3x$  for  $x = 1, 2, \dots, 20$  and store the values in a vector. Print the vector with the function `print()`. Report the length of the vector with the function `length()`.

```
x <- 1:20
print(3 * x)
```

```
## [1] 3 6 9 12 15 18 21 24 27 30 33 36 39 42 45 48 51 54 57 60
```

```
length(3 * x)
```

```
## [1] 20
```

(10 points) If you throw a baseball at an angle of  $45^\circ$ , at an initial velocity of 75 mph, while standing on a level field, the ball's horizontal distance  $x$  traveled after  $t$  seconds is described (neglecting air resistance) by the following equation from Newtonian physics:  $x = 27.12t$ . Furthermore, the height above the ground after  $t$  seconds, assuming the ball was initially released at a height of 5 ft, is described by  $y = 1.524 + 19.71t - 4.905t^2$ . The equations have been calibrated to give the distance  $x$  and height  $y$  in meters. The ball will hit the ground after about 4.09 seconds. Calculate a vector (say,  $x$ ) of baseball distances for a range of values of  $t$  from 0 to 4.09. Calculate a vector of baseball heights (say,  $y$ ) for the same collection of times. Make a plot of  $x$  (horizontal axis) and  $y$  (vertical axis). Read from the graph of the ball's trajectory how high and how far, approximately, the ball will travel.

```
t <- 0:4.09
x <- 27.12 * t
y <- 1.524 + 19.71 * t - 4.905 * t^2
plot(x, y)
```

(10 points) To decrease the use of insecticides in agriculture, predator insects are often released to combat insect pests. Coccinellids (lady beetles), in particular, have a voracious appetite for aphids. In a recent study (Pervez and Omkar 2005), entomologists looked at the suitability of using coccinellids to control a particular aphid, *Myzus persicae* (common name is the "green peach aphid"), a serious pest of many fruit and vegetable crops. In the study, the entomologists experimentally ascertained aphid kill rates for three different species of coccinellids: Enter the data columns above into vectors, giving them descriptive names. For each type of coccinellid, use R to construct a scatterplot (type = "p") of the feeding rate of the coccinellid versus aphid density.

```
# vectors data
cs <- c(21, 37, 65, 102, 125, 141, 154, 164, 170, 177)
ct <- c(21, 37, 60, 90, 109, 120, 129, 136, 140, 143)
pd <- c(15, 26, 42, 59, 69, 74, 79, 83, 85, 82)
# plot for each type of coccinellid
## vector data of aphid density
ad <- c(25, 50, 100, 200, 300, 400, 500, 600, 700, 800)
## plot
plot(cs, ad, type = "p", main = "the Cheilomenes sexmaculata vs Aphid density")
```

```
plot(cs, ct, type = "p", main = "the Coccinella transversalis vs Aphid density")
```

```
plot(cs, pd, type = "p", main = "the Propylea dissecta vs Aphid density")
```
